# Full Stack Web Development Program

# COURSE OUTLINE

## MODULE 5

1. Introduction to Web Development

2. Overview to HTML

3. Exploring fundamental HTML tags - 1

4. Exploring fundamental HTML tags - 2

**5. HTML containers tags**

# Titles

---

- Form Tags
- Table Tags
- List Tags
  - Ordered List
  - Unordered List
  - Definition List
- Links and Container Tags

# Learning Objectives

---

By the end of this module, you will be able to:

- Recognize the `<form>` element as used in HTML to create web forms
- Create lists both ordered and unordered using list tags

# **HTML `<form>` Tag**

## **Building Interactive Web Forms**

# Building Forms with <form> Tag

An HTML form, which is created using the <form> tag, is an essential part of any website that requires user input or interaction.

- The <form> tag is used to create an HTML form that contains input elements and allows users to submit data to a server.
- The **action** attribute specifies the URL to which the form data is sent, and the **method** attribute defines the HTTP method used for the form submission (e.g., GET or POST).

The image shows a web form titled "Complaints" with the subtitle "Help us improve our service." The form contains the following elements:

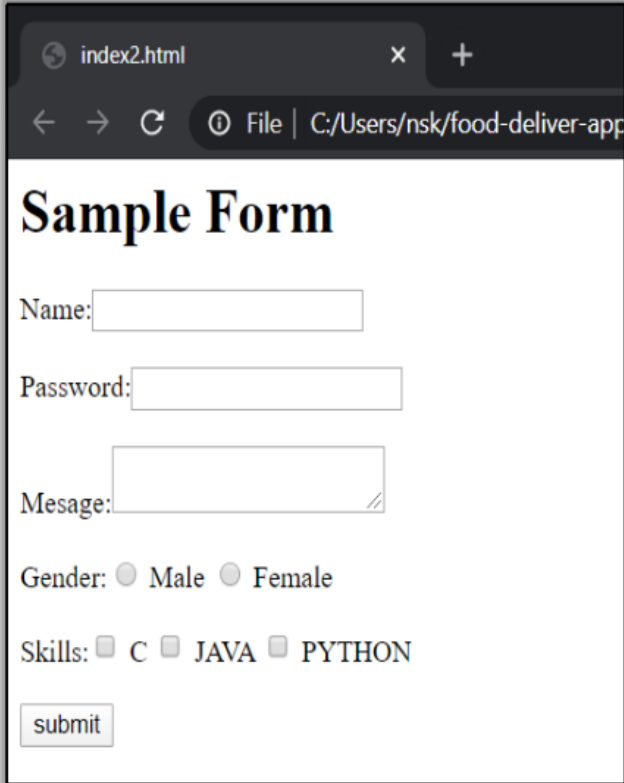

- A horizontal line separating the header from the input fields.
- A label "Full name \*" followed by two input fields. The first field is labeled "First" and the second is labeled "Last".
- A label "Email \*" followed by a single input field.
- A label "Phone" followed by a single input field.
- A label "Where did we go wrong? \*" followed by a larger text area input field.
- A red "Submit" button at the bottom.

# Building Forms with <form> Tag (contd.)

## Example:

```
<body>
<h1> Sample Form </h1>
<form method="GET">
  Name:<input type="text" id="name"> <br/><br/>
  Password:<input type="password" id="pwd"> <br/><br/>
  Mesage:<textarea id="msg"></textarea> <br/><br/>
  Gender:<input type="radio" name="gender" value="male"> Male
  <input type="radio" name="gender" value="male"> Female <br/><br/>
  Skills:<input type="checkbox" name="course" value="c"> C
  <input type="checkbox" name="course" value="java"> JAVA
  <input type="checkbox" name="course" value="python"> PYTHON <br/><br/>
  <input type="submit" value="submit">
</form>
</body>
```

## Output:

The screenshot shows a web browser window with the title 'index2.html'. The address bar shows the file path 'C:/Users/nsk/food-deliver-app'. The main content area displays the rendered form titled 'Sample Form'. The form contains the following elements: a text input for 'Name:', a password input for 'Password:', a text area for 'Mesage:', two radio buttons for 'Gender' (labeled 'Male' and 'Female'), three checkboxes for 'Skills' (labeled 'C', 'JAVA', and 'PYTHON'), and a 'submit' button.

# Structuring Data: Table Tags in HTML

HTML offers several table-related tags to structure tabular data on web pages, including `<table>` for the table itself, `<tr>` for table rows, `<th>` for table headers, and `<td>` for table data cells.

- The HTML table tag creates tables in our webpage consisting of rows and columns.
- It is defined using the `<table></table>` tag.
- `<table>` tag is a block-level element.
- Each row in a table is defined by `<tr> </tr>` tag .
- `tr` stands for table row.
- The data inside the rows are defined by using `<td> </td>` tag.
- `td` stands for table data.

Roll No.	Name	Course	Department
1	Lucy	EC	Engineering
2	Max	EE	Engineering
3	Elon	BA	Art

# Attributes of Table Tags

---

Attributes	Description
<b>align</b>	Specifies the horizontal alignment of the table. The default is left.
<b>bgcolor</b>	Specifies the background color of the table cells.
<b>border</b>	Specifies the width of the border around the table. If we do not use border, then no border will be applied to the table.
<b>cellpadding</b>	Specifies the spacing within cells, i.e. between the cell border and cell content.
<b>cellspacing</b>	Specifies the spacing between the cells of the table, i.e. space between two cells.

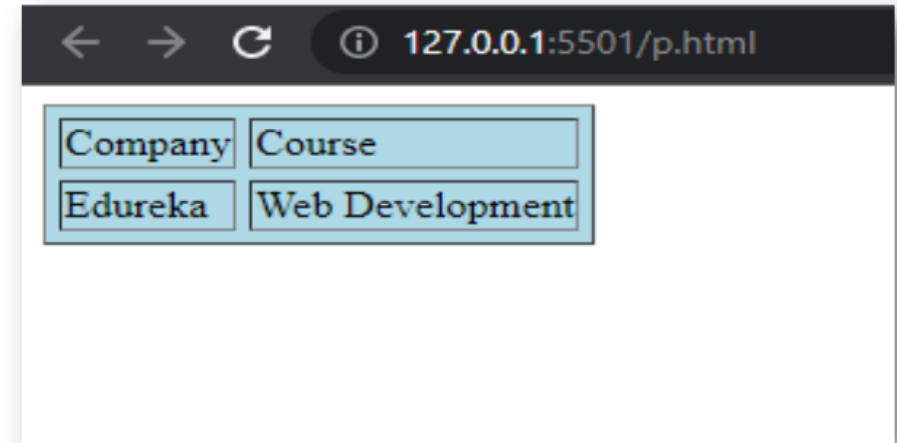

# HTML Tables – Code Example

---

Example:

```
<body>
  <table border="1px" cellspacing="5px" bgcolor="lightblue">
    <tr>
      <td>Company</td>
      <td>Course</td>
    </tr>
    <tr>
      <td>Edureka</td>
      <td>Web Development</td>
    </tr>
  </table>
</body>
```

Output:

A screenshot of a web browser window. The address bar shows the URL "127.0.0.1:5501/p.html". The browser content area displays a table with a light blue background and a 1px border. The table has two columns: "Company" and "Course". The first row contains "Edureka" under "Company" and "Web Development" under "Course".

Company	Course
Edureka	Web Development

# Creating Lists: Unordered & Ordered List Tags

HTML has tags for creating ordered and unordered lists. `<ul>` is for unordered list, `<ol>` is for ordered list, and `<li>` represents each list item.

Attributes	Description
<b>type</b>	Specifies the starting numbing style of the list.
<b>type="A"</b>	A - uppercase alphabetic.
<b>type="a"</b>	a - lowercase alphabetic.
<b>type="I"</b>	I - uppercase roman numerals.
<b>type="i"</b>	i - lowercase roman numerals.
<b>type="1"</b>	1 - decimal number. Used by default

**Attributes of Ordered List**

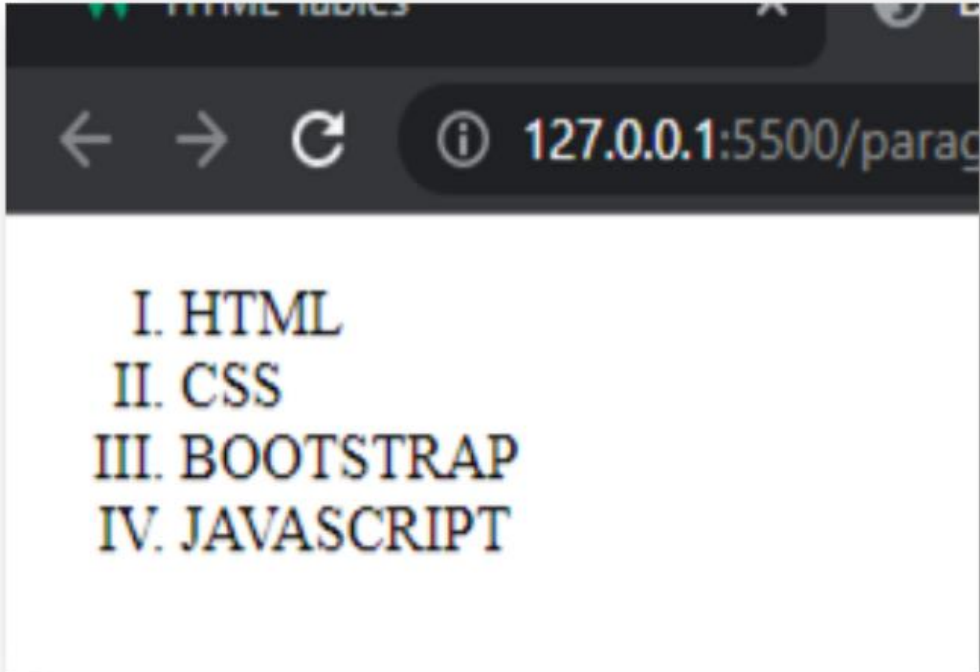

# Ordered List Example

---

Example:

```
<body>
  <ol type="I">
    <li>HTML</li>
    <li>CSS</li>
    <li>BOOTSTRAP</li>
    <li>JAVASCRIPT</li>
  </ol>
</body>
```

Output:

I. HTML  
II. CSS  
III. BOOTSTRAP  
IV. JAVASCRIPT

# Unordered List

---

Attributes	Description
<b>type</b>	Specifies the style of bullets preceding list items.
<b>type="disc"</b>	● disc - a filled-in circle, used by default.
<b>type="circle"</b>	○ disc - a circle outline.
<b>type="square"</b>	◻ square - a square.

**Attributes of Unordered List**

# Unordered List Example

Example:

```
<body>
  <ul type="square">
    <li>HTML</li>
    <li>CSS</li>
    <li>BOOTSTRAP</li>
    <li>JAVASCRIPT</li>
  </ul>
</body>
```

Output:

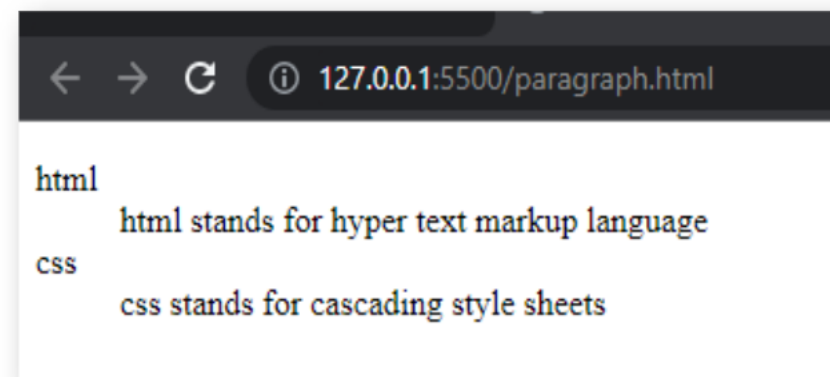

# Creating Lists: Definition List

A definition List is often used to create lists of items on your webpage using a definition list, defined by `<dl></dl>`. `<dt>` is used for the heading, and `<dd>` for the definition.

## Example:

```
<body>
  <dl>
    <dt>html</dt>
    <dd>html stands for hyper text markup language</dd>
    <dt>css</dt>
    <dd>css stands for cascading style sheets</dd>
  </dl>
</body>
```

## Output:

# Hyperlink Tag : <a> Anchor Tag

The <a> element in HTML is used to construct hyperlinks to other web pages, resources, or files. Web navigation relies on hyperlinks, which let users jump from page to page.

**Syntax:**

```
<a href="https://www.example.com">Link Text</a>
```

## Attributes:

- **href attribute:** This attribute specifies the destination URL or the resource the link points to. It can be an absolute URL (e.g., *https://www.example.com*) or a relative URL (e.g., *page.html*). You can also use *mailto:* to create email links or *tel:* for telephone links.
- **Link Text:** The text between the opening <a> tag and the closing </a> tag is what users see as the clickable link text. For example, *Click Here* in `<a href="https://www.example.com">Click Here</a>`.

# Hyperlink Tag : <a> Anchor Tag (contd.)

## Attributes (Contd.) :

- **Target Attribute: (Optional):** The target attribute specifies how the linked resource should be displayed. Common values include:
  - **\_self (default):** Opens the linked page in the same browser window or tab.
  - **\_blank:** Opens the linked page in a new browser window or tab.
  - **\_parent:** Opens the linked page in the parent frame or window.
  - **\_top:** Opens the linked page in the full body of the window, canceling all frames.

## Example usage of <a> element

```
<!-- Link to an external website -->
<a href="https://www.example.com">Visit Example.com</a>

<!-- Link to an internal page (relative URL) -->
<a href="about.html">About Us</a>

<!-- Create an email link -->
<a href="mailto:info@example.com">Contact Us</a>

<!-- Create a telephone link -->
<a href="tel:+1234567890">Call Support</a>
```

# Heading Tags – Highlight Key Information

Heading tags in HTML are a set of elements used to define headings or titles for different sections of a web page, essential for structuring the content and providing hierarchy to the text on a webpage.

From `<h1>` to `<h6>`, heading tags are the highest level (main heading) and lowest level (subheading). Common heading tags are:

- **`<h1>`:** The top-level heading tag is primarily used for the web page's major title or heading. Each page should have one `<h1>` that explains its main topic or purpose.
- **`<h2>`:** It is used for supplementary headings or subheadings on the page. Although less critical than `<h1>`, it is commonly used to separate text into significant sections.
- **`<h3>` to `<h6>`:** These tags are used for further subheadings within the content, and to create a hierarchical structure based on their level of importance, with `<h3>` being higher than `<h4>`, and so on.

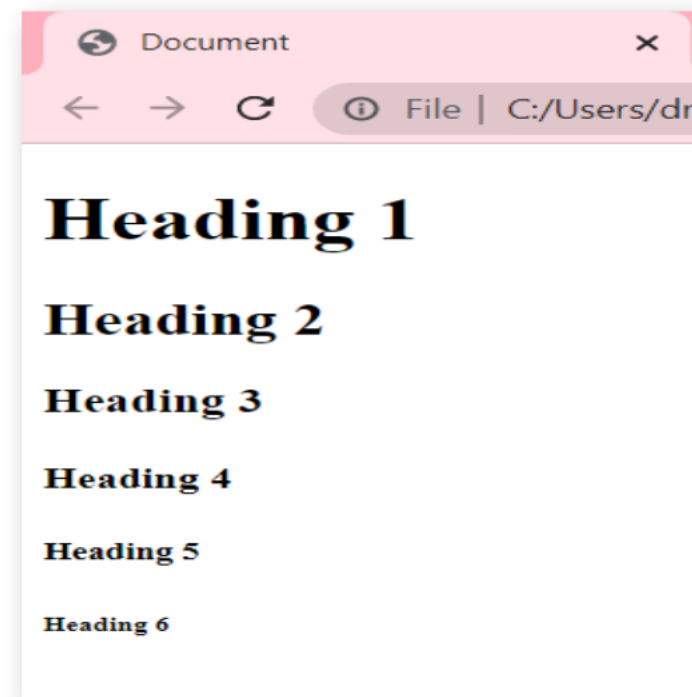

# Heading Tags – Highlight Key Information (contd.)

Example:

```
<body>  
  <h1>Heading 1</h1>  
  <h2>Heading 2</h2>  
  <h3>Heading 3</h3>  
  <h4>Heading 4</h4>  
  <h5>Heading 5</h5>  
  <h6>Heading 6</h6>  
</body>
```

Output:

# From Words to Stories: <p> Tag's Significance

In HTML, a paragraph is represented by the <p> tag, which stands for "paragraph" and defines a block of text or content. It's a staple of web page formatting and structure, and one of the most fundamental HTML tags.

## Syntax:

```
<p> // Block of text or content </p>
```

- The <p> tag is a block-level element, which means it typically starts on a new line and takes up the full width available within its containing element (like a <div> or the main body of an HTML document).
- Paragraphs are used to structure textual content on web pages, including articles, blog posts, descriptions, etc.

## Example:

```
<body>  
  <h1>paragraph1:</h1>  
  <p>this is an example of how paragraph tag works</p>  
  <h1>Paragraph2</h1>  
  <p>this is an example of how paragraph tag works</p>  
</body>  
</html>
```

## Output:
